**Phase Behavior of Surface-Active Solute**

**Introduction**
Surface-active agents (surfactants) are ubiquitous in industrial, cosmetic and pharmaceutical products and living systems use naturally occurring surfactants, such as lecithin and phospholipids. Most discussions of surfactants are concerned with relatively low concentrations so that the system contains “simple” surfactant species, such as monomers and their basic “aggregates” (micelles). However, this is only a part of the total phase behavior of binary systems containing water and a surfactant. Many such solutes form elaborate structures at higher concentrations. The milky appearance of soap solutions does not arise because of micelles (they are too small to scatter a significant quantity of light) but is due to the presence of larger entities termed mesomorphic phases (mesophases). These are anisotropic structures in which one or two dimensions are highly extended.

In the food industry, certain surfactants are used as emulsifiers, including the Spans and Tweens, which are used extensively and can form mesophases in water. In addition, oil lipids (monoglycerides, phospholipids and sterol esters) are used and can also form mesophases that promote emulsion stability and stabilize aerated systems (i.e., whipped cream), improve consistency, texture and shelf-life and modify rheological properties.

Surfactant mesophases are lyotropic, i.e., their structure is determined by specific interactions between the surfactant molecules. Natural fatty-acid soaps and phospholipids can also form thermotropic mesophases; here the properties are determined by the temperature of the system. The various lyotropic structures that may occur as the concentration of a solute increases in a binary aqueous system are shown schematically in Figure 1. When the surfactant concentration in aqueous solution exceeds ~10% by weight, micelle-micelle interactions become significant and the simple spherical structures generally undergo conversion first to infinite cylinders and then to multi-bilayers. The middle phase consists of surfactant molecules grouped into rod-like clusters of indefinite length that are arranged in a hexagonal packing arrangement comprising typically an oil-core, where the lipophilic groups form the core and hydrophilic groups lie on the surface; it exhibits optical birefringence (opalescence). Most surfactant/water systems are of this type. In the viscous isotropic phase, the molecules pack in spheres that then assemble into a face-centered or body-centered cubic lattice structure. Cubic phases are the most difficult to detect and characterize and are the least well-known. However, they are useful in drug delivery.

The neat phase possesses a lamellar structure in which water is sandwiched between the layers of amphiphilic molecules. Molecules with lamellar packing may be perpendiculat to the plane or tilted (the angle of tilt is a function of the water content). Except for the fact that the chains have a disordered conformational structure, this phase closely resembles the typical crystalline state of pure surfactant. The level of order can vary. For example, four different neat lamellar phases have been identified in the dipalmitoylphosphatidylcholine - water system. The terms “middle” and “neat” phases were originally described by 19th century soap-boilers!

The phase behavior of concentrated surfactant solutions is complex and is strongly influenced by the molecular geometry of the surfactant. This latter aspect is of considerable importance to biological membranes. Further, it is often tacitly assumed that surfactant solutions are in instantaneous equilibrium with respect to micelle, or other structure formation, when changes in conditions (degree of dilution, temperature, salt addition, etc) are made. However, the times required for the formation of, or disruption to, an equilibrium phase structure in concentrated surfactant solutions may require several days.

**Phase Diagrams**
A phase diagram is a graphical portrayal of information that answers three basic questions: (i) how many phases exist? (ii) what is the qualitative nature of each phase? and (iii) what is the composition of each phase? From a properly constructed diagram, one can obtain by inspection or calculation the answers. Other kinds of information can also be deduced such as the proportion of the total system in each of the co-existing phases and the temperature dependence.

Phase diagrams are used to specify the temperature and concentrations at which various structures exist at equilibrium. In binary diagrams, by convention, temperature is placed on the ordinate and composition on the abscissa, with water to the left and surfactant to the right. Figure 2 is a binary diagram of condensed phases of an alkyl polyoxyethylated (C2-E2) nonionic solute in water; the lines designate the experimental boundaries; 2L is two isotropic liquids; S is one isotropic liquid; M is a middle phase; I+M is ice plus middle phase; I+C is ice plus crystals; P is a neat phase.

The middle and neat LC phases occur at high concentrations and are more extensive, on a phase

diagram, the longer the alkyl chain. A vertical line of constant composition but variable temperature is termed an isopleth. The boundaries that delineate the range of existence of the various phases assume distinctive shapes; typically the region is bullet- or dome-shaped. The same LC states found within surfactant - water systems are also found within surfactant – electrolyte - water systems.

In ternary systems in which the third component is an alkane or fatty derivative (such as an acid, alcohol or amide) the same associated structures can be identified. Indeed, adding an “oil” to a surfactant-water system often forms a more complete set of LC states than is possible without the oil. Figure 3 illustrates the ternary system of water - sodium octyl sulfonate - decanol (at 20°C). The surfactant has limited solubility both in water and decanol but the alcohol is not soluble in water. The aqueous phase, L1, contains hydrophilic micelles; at concentrations below the critical micelle concentration (CMC) it contains no decanol. The alcohol phase, L2, contains inverse (lipophilic) micelles. The phases N (neat, displaying lamellar structure) and M (middle, displaying two-dimensional hexagonal structure) are both liquid crystals. This diagram contains features that occur as general behavior in all such ternary systems of surface-active solutes, water and fatty-acid derivatives. Changes of temperature, salinity, fatty-acid derivative and structure of the surfactant cause systematic shifts in the relative positions of the one-phase regions.

The phase behavior of water-oil-surfactant systems represented using a ternary diagram can be used to determine the composition required to create, for example, a microemulsion. Once the composition is determined, microemulsions are easy to manufacture reproducibly; they are also transparent and behave like a clear liquid with low viscosity and, unlike coarse emulsions, they are thermodynamically, i.e. indefinitely, stable.

The experimental methods for determining phase information, analyzing two- and three-component phase diagrams and calculating phase ratios is beyond the scope of this brief; an extensive and in-depth description of these matters can be found in reference 5.

Phase information is possibly the most useful kind of physical data that exists for surfactant systems. A few practical examples serve to illustrate this.

1. The trajectory of any physical process in which composition and/or temperature are varied (within a defined system) may be charted on that system's phase diagram. Heating or cooling any system of fixed composition corresponds to rising or falling along an isopleth in a phase diagram (Figure 2). The vaporization of solvent from a solution corresponds to moving to the right; dilution of a system is depicted by moving to the left.

2. Phase heterogeneity underlies most separation processes. In soap-making, the hot “neat” liquid crystal phase is used to form framed soap bars after separation from the lye phase and cooling. In fat refining, polar lipid impurities are removed from fats by first precipitating the liquid crystal and then removing it by filtration.

3. Phase behavior dictates the selection of suitable components for use in a product. Components of liquid detergents, which are ordinarily concentrated solutions, must be selected with both phase behavior and utility in mind.

4. The utility of surfactants is often limited by inadequate solubility; phase information provides a complete (both qualitative and quantitative) description. Whenever, a solubility boundary lies well below an intended use concentration it will result in impaired effectiveness of the material for the intended use.

5. Control of “interfacial properties” via control of bulk phase composition is possible. Foam stabilization is exceptionally good when the system has two phases, one being a small amount of a lamellar LC phase.

6. Perturbations in hydrophilic or lipophilic group structural features alter phase boundary locations in surprisingly predictable ways. Phase behavior can distinguish non-surfactant amphiphilic molecules from true surface-active solutes.

Conclusion

In conclusion, the existence of predictable relationships between phase behavior and structure is potentially very significant, for where the need for a specific kind of phase behavior can be stated then molecules can be efficiently selected or designed to fill this need.

References

For over 15 years Particle Sciences has been developing innovative drug delivery solutions for our clients. We are a full service CRO providing complete formulation, GMP/GLP analytic, bioanalytic and clinical trial material manufacturing. We specialize in nanoparticulate, semisolids and combination products.

**Unique Capabilities**

Fine-particle and nanoscale systems have been a focus of Particle Sciences since its inception in 1991. We work with all dosage forms and offer unique expertise in topical and mucosal therapeutics.

**Technology**

Our staff has extensive experience in drug delivery formats including micro- and nano-particulates, emulsions, suspensions, encapsulated API’s and polymeric controlled release dosage forms. Particle Sciences has all the necessary instrumentation and in-house expertise to produce and characterize these systems. Additionally we have a dedicated combination-product team with full compounding and injection molding capabilities.

**Exceptional Staff**

Our talented staff come from a variety of backgrounds and includes physicians, engineers, and doctorate-level surface, analytic, material science and polymer scientists. Combined, the senior management team at Particle Sciences has well over 150 years experience in innovative drug development.

**Facilities**

Particle Sciences is equipped with state-of-the art formulation equipment, analytic and bioanalytic instrumentation. Housed in 15,000 sqft, Particle Sciences provides complete services from API characterization through to clinical trial material manufacture of both sterile and non-sterile drug products.

**Integrated Process**

By structuring a program of pre-formulation, formulation, analytic, bioanalytic and manufacturing services, Particle Sciences provides clients with a powerful, integrated solution to most efficiently take a drug from discovery to the clinic. Each project has a dedicated team and leader to manage the project from start to finish.

**Problem-solving**

With years of experience to draw from, Particle Sciences can confidently handle difficult APIs, complicated intellectual property terrains and challenging delivery goals to arrive at the simplest, most efficient solution to our client's needs.

**Efficient**

Clients with demanding performance requirements and timelines will benefit from the speed, efficiency and quality that Particle Sciences delivers.

**Collaborative**

Particle Sciences maintains an "open door policy" with its clients and provides ready access to lab facilities and staff. Clients can consider Particle Sciences an expert extension of their in-house development team.

**Client-focused**

Each project receives individualized attention. Particle Sciences prefers to take a consultative approach to ensure positive project outcomes and the highest levels of client satisfaction. Projects are overseen and coordinated by a dedicated project manager in conjunction with a cross-functional team.
